INTRODUCTION - Part II

I C – Image encoding

Compression techniques

- La scelta della tecnica di compressione da impiegare dipende dal contesto applicativo e da una serie di parametri legati al tempo di compressione al fattore di compressione ed alla fedelta' dell'informazione ripristinata. In generale:
 - documenti testuali: compressione lossless
 - dati per analisi numerica: compressione lossless
 - Programmi: compressione lossless
 - immagini destinate a tipografia: compressione lossless
 - immagini destinate al WEB: compressione lossy
 - Video: compressione lossy
 - Audio: compressione lossy
- L'impiego di tecniche lossy e' in molti casi obbligatorio e rappresenta l'unica possibile soluzione qualora si vogliano dei fattori di compressione molto elevati.

■ Immagine 146 x 184 con 75 colori. Dimensione file:

- Teorica con 8 bpp: 26864 byte
- Teorica con 24 bpp: 80592 byte
- PPM (24 bpp) : 80674 byte
- GIF (8 bpp): 3585 byte (FC=22.48)
- JPG (24 bpp): 4805 byte (FC=16.77)
- PPM.ZIP (24 bpp): 3698 byte (FC=21.79)

Immagine 244 x 334 con 31322 colori. Dimensione file:

Teorica con 8 bpp: 81496 byte

Teorica con 24 bpp: 244488 byte

PPM (24 bpp) : 244620 byte

GIF (8 bpp): 49613 byte (FC=4.92)

JPG (24 bpp): 16352 byte (FC=14.95)

PPM.ZIP (24 bpp): 190977 byte (FC=1.28)

Lossless compression

A thick, horizontal yellow brushstroke underline that spans the width of the slide, starting below the title and extending to the right edge.

RUN-LENGTH ENCODING

■ Con questa tecnica si sostituisce una sequenza di simboli uguali con un solo simbolo accompagnato dal numero di volte che questo compare consecutivamente:

pppppppppppp pppppppppppp pppppppppppp diventa \$11p \$11p \$11p

■ E' necessario definire l'impiego di un carattere speciale (in questo caso \$). L'intero file puo' essere codificato con la sequenza:

\$11r \$11r \$11r
\$11p \$11p \$11p
\$11c \$11c \$11c

Totale caratteri: $9+9+9 = 27$

Totale numeri: $3+3+3=9$

Dimensione file: $36\text{Byte} = 288\text{bit}$

■ Questa tecnica puo' essere impiegata anche per la codifica di immagini, traendo vantaggio dall'occorrenza di pixel consecutivi di ugual colore.

HUFFMAN ENCODING

- Invece di rappresentare ogni carattere con un Byte, e' possibile associare ad ogni carattere un codice. Ai caratteri piu' frequenti viene associato un codice di pochi bit, mentre la lunghezza del codice cresce al diminuire della frequenza del carattere.
- Il codice da associare ad ogni carattere puo' essere determinato costruendo una struttura ad albero binario sulla base delle frequenze dei singoli caratteri.

- Si consideri il caso di un documento in cui compaiono 5 caratteri A, B, C, D, E. La frequenza dei singoli caratteri e': $f(A)=0.45$, $f(B)=0.25$, $f(C)=0.15$, $f(D)=0.05$, $f(E)=0.10$. Il corrispondente albero binario e':

- Pertanto i 5 caratteri vengono cosi' codificati:

- A: 0
- B: 10
- C: 110
- D: 1110
- E: 1111

ARITHMETIC ENCODING

- E' una variante della codifica di Huffman in grado di consentire maggiori rapporti di compressione a fronte della perdita di poter accedere non sequenzialmente al file compresso.
- A questa categoria appartiene un particolare algoritmo di compressione chiamato LZW (Lempel-Zif-Welsh) ed impiegato nel formato GIF di compressione delle immagini.

■ SOFTWARE DI COMPRESSIONE

■ UNIX:

- **compress / uncompress (filename.Z)**
- **gzip / gunzip (filename.gz)**
- **zip / unzip (filename.zip)**

■ MSwindows:

- **pkzip / pkunzip (filename.zip)**
- **zip / unzip (filename.zip)**
- **rar (filename.rar)**
- **arj (filename.arj)**
- **zoo (filename.zoo)**
- **lharc (filename.lha)**

■ Macintosh:

- **stuffit (filename.sit)**
- **sea (filename.sea)**
- **zip / unzip (filename.zip)**

Lossy compression

A thick, horizontal yellow brushstroke underline that spans the width of the slide, starting below the title and extending to the right edge.

SECT A JPEG ENCODING

A thick, horizontal yellow brushstroke underline that spans the width of the slide, positioned directly beneath the title text.

■ JPEG uses transform coding, it is largely based on the following observations:

■ **Observation 1:** A large majority of useful image contents change relatively slowly across images, i.e., it is unusual for intensity values to alter up and down several times in a small area, for example, within an 8 x 8 image block. Translate this into the spatial frequency domain, it says that, generally, lower spatial frequency components contain more information than the high frequency components which often correspond to less useful details and noises.

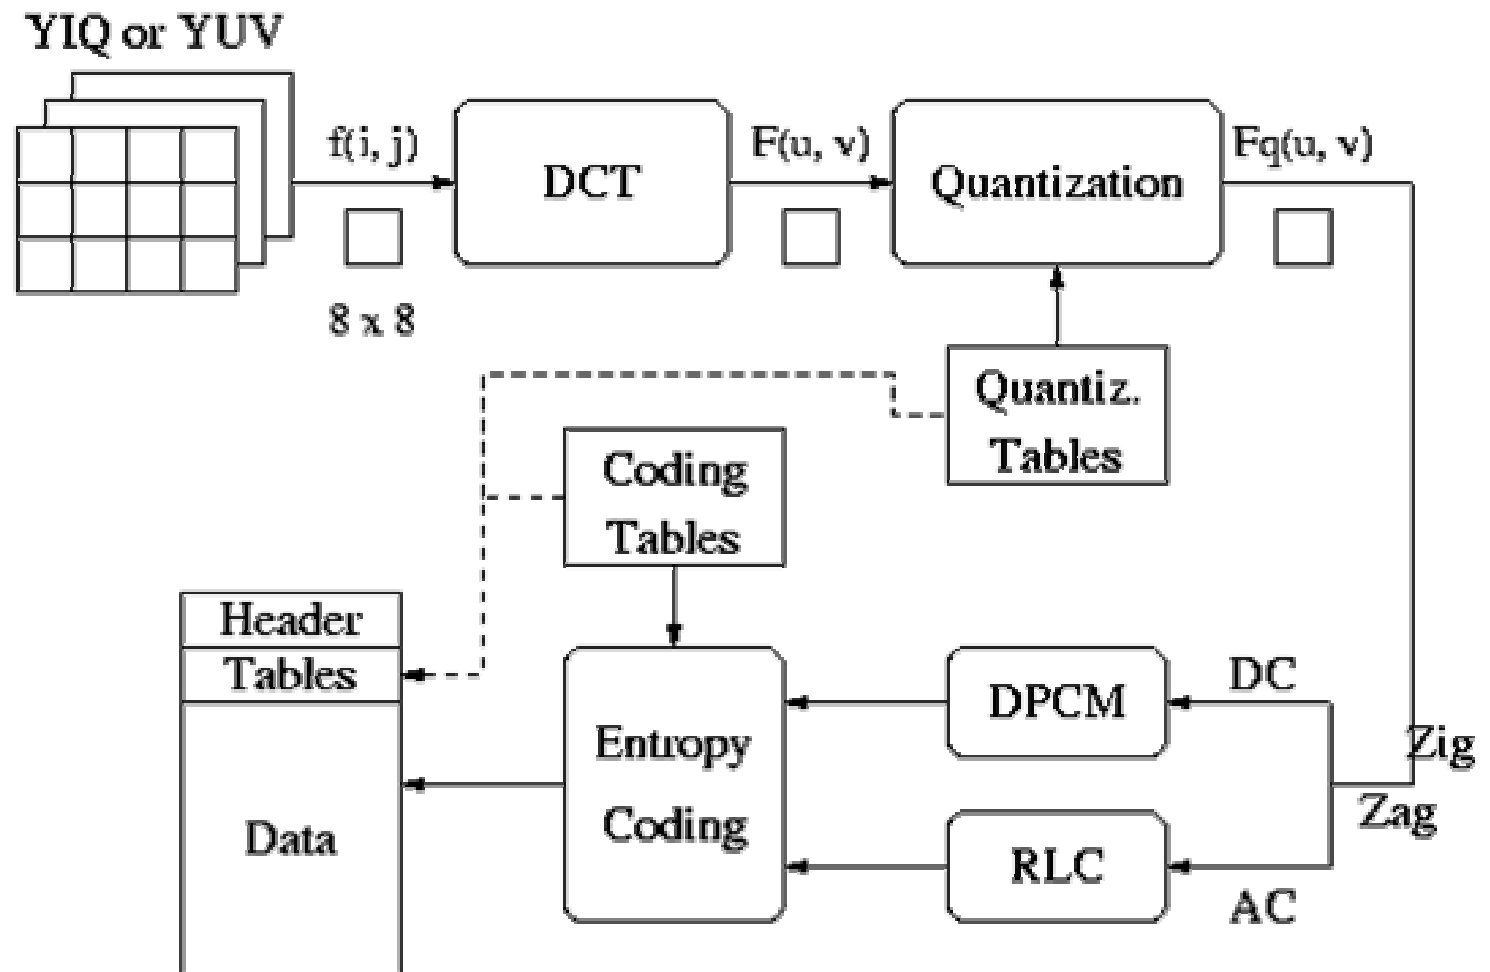

■ **Observation 2:** Pshchophysical experiments suggest that humans are more receptive to the loss of higher spatial frequency components than the loss of lower frequency components.

■ Major Steps

- DCT (Discrete Cosine Transformation)
- Quantization
- Zigzag Scan
- Entropy coding
 - Coefficient encoding
 - DPCM on DC component
 - RLE on AC Components
 - Huffman Coding

JPEG chain

DCT (Discrete Cosine Transformation)

- Apply DCT to 8x8 image blocks
- If the image size is not a multiple of 8, then add copies of the last row or column until a multiple of 8 is reached. This makes both tone and luminance of the 8x8 block not change too much after DCT, as it would be if these elements were set to 0.

DCT allows to shift from spatial domain to frequency domain:

$F(u,v)$ is the DCT coefficient of the 8x8 block in the (u,v) position of the 8x8 matrix that encodes the transformed coefficients.
 $f(i,j)$ is the value that is present in the (i,j) position of the 8x8 block

Discrete Cosine Transform (DCT):

$$F(u, v) = \frac{\Lambda(u)\Lambda(v)}{4} \sum_{i=0}^7 \sum_{j=0}^7 \cos \frac{(2i+1) \cdot u\pi}{16} \cdot \cos \frac{(2j+1) \cdot v\pi}{16} \cdot f(i, j)$$
$$\Lambda(\xi) = \begin{cases} \frac{1}{\sqrt{2}} & \text{for } \xi = 0 \\ 1 & \text{otherwise} \end{cases}$$

Inverse Discrete Cosine Transform (IDCT)

$$\hat{f}(i, j) = \frac{1}{4} \sum_{u=0}^7 \sum_{v=0}^7 \Lambda(u)\Lambda(v) \cos \frac{(2i+1) \cdot u\pi}{16} \cdot \cos \frac{(2j+1) \cdot v\pi}{16} \cdot F(u, v)$$
$$\Lambda(\xi) = \begin{cases} \frac{1}{\sqrt{2}} & \text{for } \xi = 0 \\ 1 & \text{otherwise} \end{cases}$$

- Why DCT not FFT? -- DCT is like FFT, but can approximate linear signals well with few coefficients.

The 64 (8 x 8) DCT basis functions

- To compute DCT, factoring reduces the problem to a series of 1D DCTs:

$$F[u, v] = \frac{1}{2} \sum_i A(u) \cos \frac{(2i+1)u\pi}{16} G[i, v]$$

$$G[i, v] = \frac{1}{2} \sum_j A(v) \cos \frac{(2j+1)v\pi}{16} f[i, j]$$

Quantization

- To reduce number of bits per sample quantization is used:
$$F'[u, v] = \text{round} (F[u, v] / q[u, v])$$

Where $q(u,v)$ is the quantization matrix and $F(u,v)$ is the DCT coefficient matrix. Different quantization matrices are used for different color codes.
- Example: $101101 = 45$ (6 bits)
 $q[u, v] = 4 \rightarrow$ Truncate to 4 bits: $1011 = 11$
- Quantization error is the main source of the Lossy Compression.

■ **Uniform Quantization** Each $F[u,v]$ is divided by the same constant N .

■ **Non-uniform Quantization** Eye is most sensitive to low frequencies (upper left corner), less sensitive to high frequencies (lower right corner)

| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Coefficienti dequantizzati

$$F^{Q'}(u,v) = F^Q(u,v) \cdot Q(u,v)$$

- 
- As a result of quantization we have a 8×8 matrix with many elements equal to 0. non null coefficients are all in the upper left corner.
 - This suggests to transform the 8×8 matrix into a 64 element vector using a zig-zag order.

Zig-zag scan

Zig-Zag scan is used to group low frequency coefficients in top of the vector: Maps 8x8 to 1x64 vector

Coefficient encoding

- Differential Pulse Code Modulation (DPCM) on the DC component
 - DC component is large and varied, but often close to the value of the DC component of the previous block.
 - According to this we encode the difference between the previous and the current 8 x 8 block (DC diff)
- Run Length Encoding (RLE) on AC components
 - Many of the AC coefficients are equal to 0.
 - According to this they are encoded using RLE, which counts the number of consecutive 0s. A minimum of 0 to a maximum of 16 consecutive 0s is allowed. In the latter case the special symbol (15,0) is used. The end of block is encoded with (0,0).

- For the DC component (DC diff) we build the pair: (SIZE, AMPLITUDE)
- SIZE is the number of bits needed to represent the DC diff coefficient; AMPLITUDE is the DC diff.

| ----- | |
|-------|------------------------|
| SIZE | Value |
| ----- | |
| 1 | -1, 1 |
| 2 | -3, -2, 2, 3 |
| 3 | -7..-4, 4..7 |
| 4 | -15..-8, 8..15 |
| . | . |
| . | . |
| 10 | -1023..-512, 512..1023 |
| ----- | |

Example: if DC value is 4, 3 bits are needed.

- 
- For the AC components we use the following representation: (RUNLENGTH, SIZE) (AMPLITUDE)
 - RUNLENGTH is the number of consecutive 0 (from 0 to 15), SIZE has the same meaning as for the DC coefficient, AMPLITUDE is the actual value for nonzero AC coefficients-

Sequenza di simboli codificati

Huffman encoding

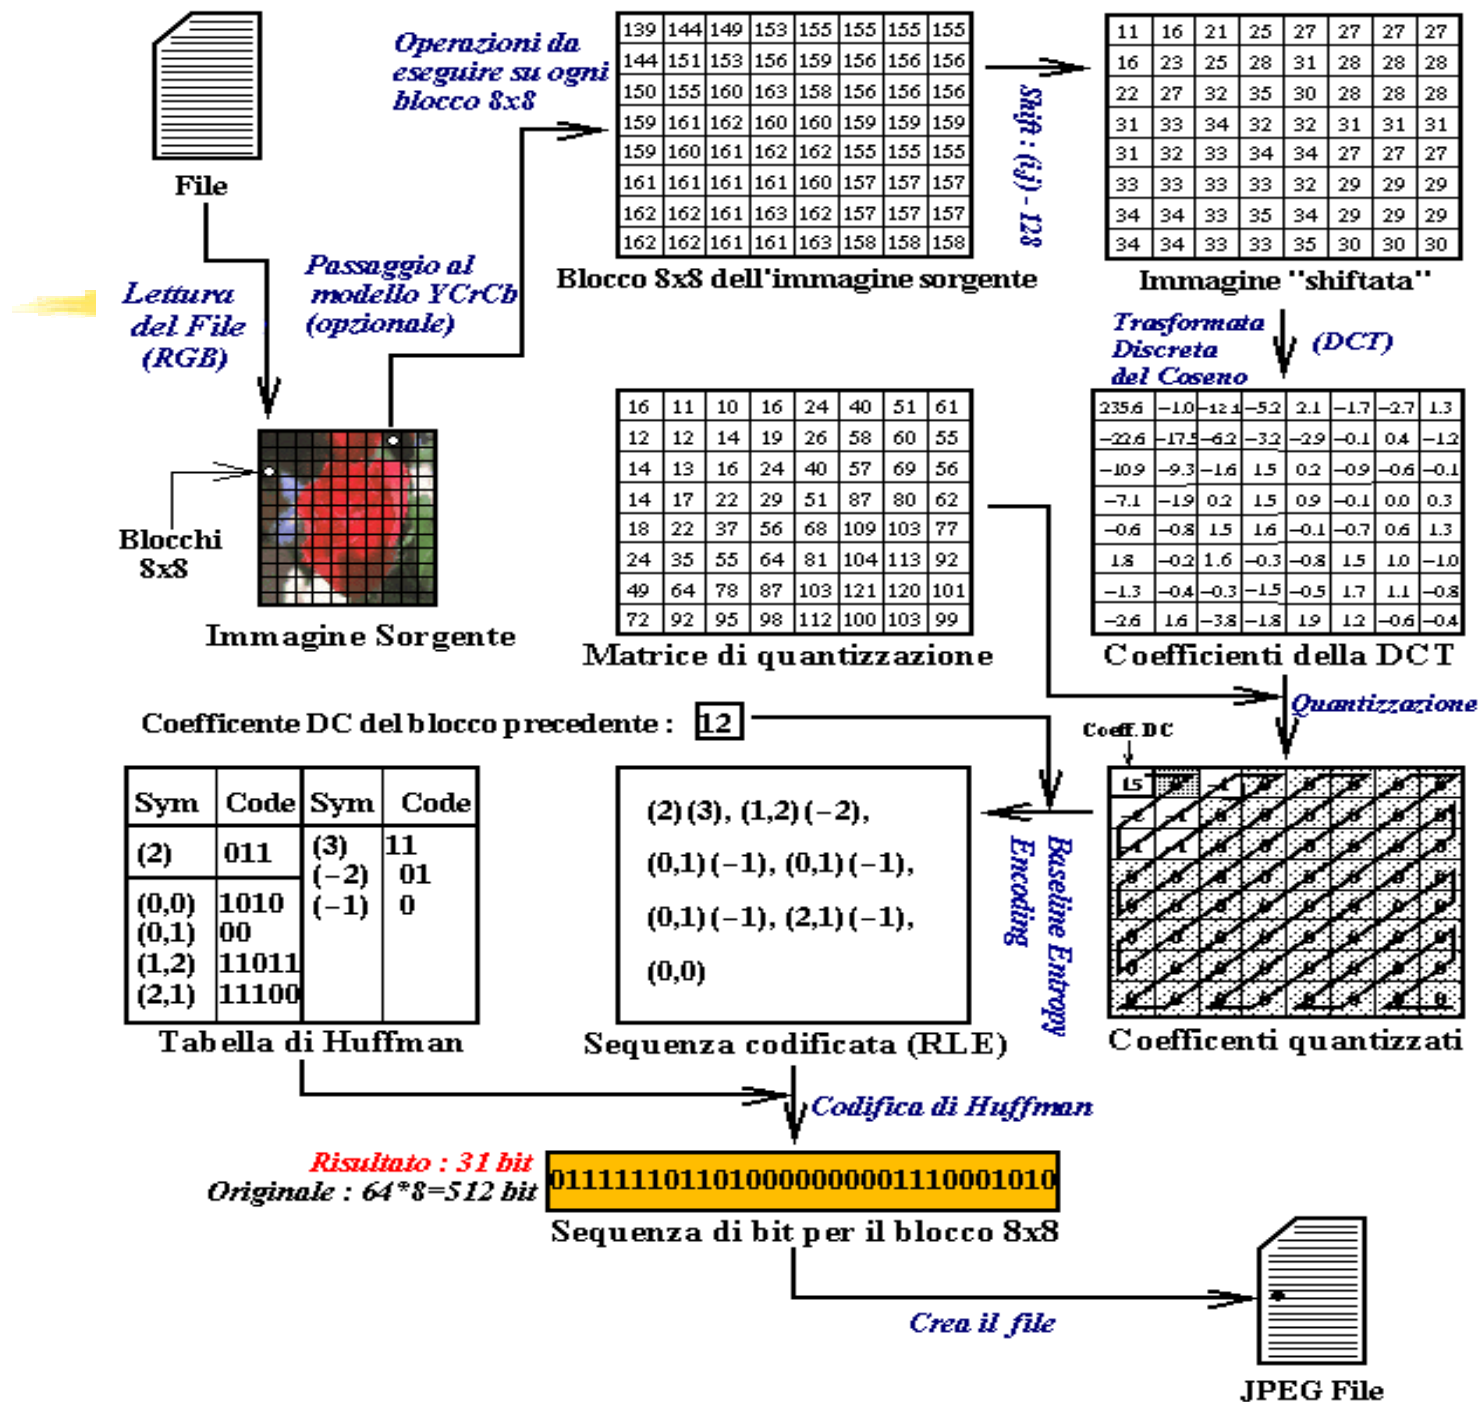

- After we have encoded every block, we have a sequence of symbols:
 - Symbol 1: (SIZE) or (RLE, SIZE)
 - Symbol 2: (AMPLITUDE)
- These symbols are further encoded using the Huffman encoding to reduce the number of data.
- Most frequent symbols are encoded with shorter codes. Less frequent with longer ones. Huffman tables provide codes for every symbol of the sequence. Huffman tables are different for DC and AC symbol 1.
- Huffman Tables can be custom (sent in header) or default.

Symbol1 and Symbol2 encoding

Byte stuffing

Progressive JPEG

- The DCT progressive mode of operation consists of the same FDCT and Quantization steps that are used by DCT sequential mode. The key difference is that each image component is encoded in multiple scans rather than in a single scan.

- 
- After each block of DCT coefficients is quantized, it is stored in a coefficient buffer memory. The buffered coefficients are then partially encoded in each of multiple scans.
 - The first scan(s) encode a rough but recognizable version of the image which can be transmitted quickly in comparison to the total transmission time, and are refined by succeeding scans until reaching a level of picture quality that was established by the quantization tables.

- 
- There are two complementary methods by which a block of quantized DCT coefficients may be partially encoded.
 - First, only a specified band of coefficients from the zig-zag sequence need be encoded within a given scan. This procedure is called .spectral selection, because each band typically contains coefficients which occupy a lower or higher part of the spatial-frequency spectrum.
 - Secondly, the coefficients within the band need not be encoded to their full quantized accuracy in a given scan (first the N most significant bits and the less significant in successive scans)

c) progressive encoding: spectral selection

d) progressive encoding: successive approximation

Figure 11. Spectral Selection and Successive Approximation Methods of Progressive Encoding

■ The quantized DCT coefficient information can be viewed as a rectangle for which the axes are the DCT coefficients (in zig-zag order) and their amplitudes.

■ Spectral selection slices the information in one dimension and successive approximation in the other.

Hierarchical JPEG

- The hierarchical mode provides a pyramidal. encoding of an image at multiple resolutions, each differing in resolution from its adjacent encoding by a factor of two in either the horizontal or vertical dimension or both.

The encoding procedure can be summarized as follows:

- 1) Filter and down-sample the original image by the desired number of multiples of 2 in each dimension.
- 2) Encode this reduced-size image using one of the sequential DCT, progressive DCT, or lossless encoders described previously.
- 3) Decode this reduced-size image and then interpolate and up-sample it by 2 horizontally and/or vertically, using the identical interpolation filter which the receiver must use.
- 4) Use this up-sampled image as a prediction of the original at this resolution, and encode the difference image using one of the sequential DCT, progressive DCT, or lossless encoders described previously.
- 5) Repeat steps 3) and 4) until the full resolution of the image has been encoded.

- 
- Hierarchical encoding is useful in applications in which a very high resolution image must be accessed by a lower-resolution display.
 - An example is an image scanned and compressed at high resolution for a very high-quality printer, where the image must also be displayed on a low-resolution PC video screen.

Lossless JPEG

- Lossless JPEG doesnot use DCT.
- It encodes the difference between the actual value of each pixel and its predicted value. The predicted value is provided by an appropriate function (e.g. the average) based on the modified values of the pixels above and left.
- The sequence is encoded with the Huffman code

The JPEG Bitstream

Frame header:

sample precision

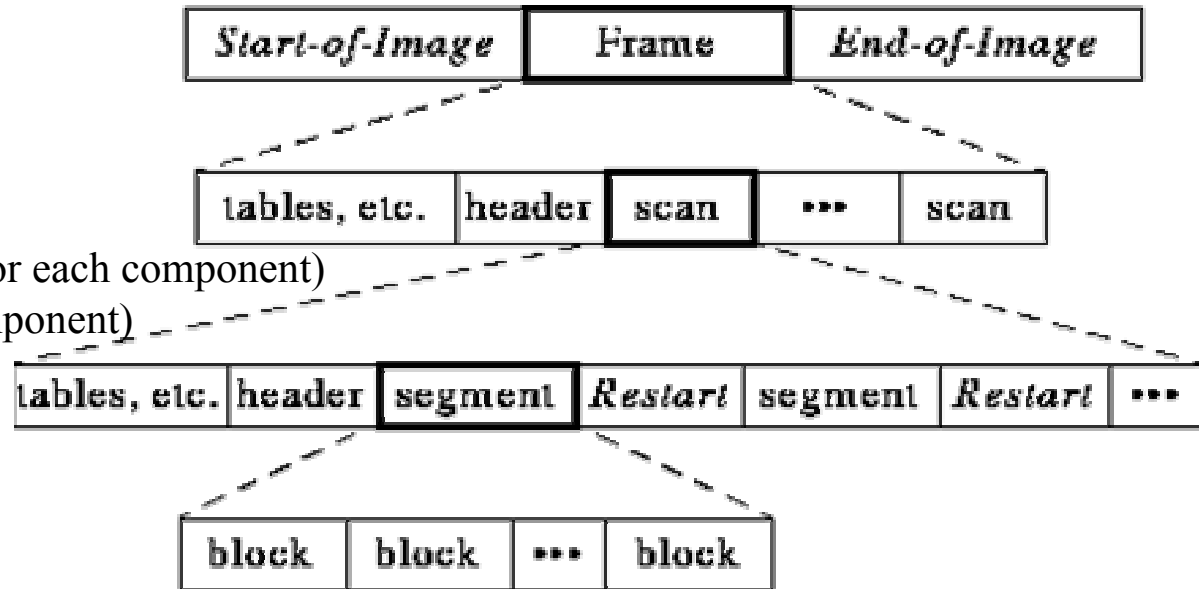

(width, height) of image

number of components

unique ID (for each component)

horizontal/vertical sampling factors (for each component)

quantization table to use (for each component)

Scan header

Number of components in scan

component ID (for each component)

Huffman table for each component (for each component)

Misc. (can occur between headers)

Quantization tables

Huffman Tables
